# Lesson 1 : Probability Review

> **Bernouilli Shortcut :** If a random variable can only assume two values $a$ and $b$ with probability $q$ and $1 - q$, then is variance is
$q(1 - q)(b - a)^2$

# Lesson 2 : Parametric Distributions

> **Transformations :**
> - Transformed : $\tau > 0$
> - Inverse : $\tau = -1$
> - Inverse-Transformed : $\tau < 0, \tau \neq 1$

# Lesson 4 : Markov Chains

> **Chapman-Kolmogorov :**
$$P_{ij}^{(n+m)} = \sum_{k=0}^{\infty} P_{ik}^{(n)} P_{kj}^{(m)}$$

> **Gambler's ruin :** Let N the target and j the actual status.
$$p_j = \begin{cases} \dfrac{j}{N} & , r = 1 \\ \dfrac{r^j - 1}{r^N - 1} & , r \neq 1 \end{cases}$$
où $r = \dfrac{q}{p}$, p : winning prob.

> **Algorithmic efficency :** with $N_j$ = number of steps from $j^{th}$ solution to best solution.
$$\mathrm{E}[N_j] = \sum_{i=1}^{j-1} \frac{1}{i}$$
$$\mathrm{Var}(N_j) = \sum_{i=1}^{j-1} \left(\frac{1}{i}\right)\left(1 - \frac{1}{i}\right)$$
As $j \to \infty$, $\mathrm{E}[N_j] \to \ln j$, $\mathrm{Var}(N_j) \to \ln j$

# Lesson 5 : Markov Chain Classification

> An **absorbing** state is one that cannot be exited.
> State j is **accessible**$(i \to j)$ from state i if $p_{ij}^n > 0$,
$\forall n \geq 0$.
> Two states **communicate** if $i \leftrightarrow j$.
> A **class** of states is a maximal set of state that communicate with each other.
> A Markov chain is **irreductible** if it has only one class.
> A state (class) is **recurrent** if the probability of reentering the state is 1. $\sum_{n=1}^{\infty} p_{ii}^{(n)} = \infty$
> A state (class) si **transcient** if it is not recurrent.
$\sum_{n=1}^{\infty} p_{ii}^{(n)} < \infty$
> A finite Markov Chain must have at least one recurrent class. If it is irreductible, then it is recurrent.

# Lesson 6 : Markov Chains Limiting Probability

> A chain is **positive recurrent** is the expected number of transitions until the state occur is finite, **null recurrent** otherwise. Null recurrent mean that the long-term proportion of time in each state is 0.
> A chain is **periodic** when states occur every n periods for $n > 1$.
> A chain is **aperiodic** when the period is 1. In other world, $P_{ii}^{(1)} > 0, \forall i$
> A chain is **ergodic** when the chain is aperiodic and positive irreductible recurrent.
> **Stationary probability :**
$$\pi_j = \sum_{i=1}^{n} P_{ij} \pi_i \qquad \sum_{i=1}^{n} \pi_i = 1$$
> **Limiting probabilities :** if the chain is ergodic, then
$$\mathbf{P}^{(\infty)} = \begin{pmatrix} \pi_1 & \pi_2 & \pi_3 \\ \pi_1 & \pi_2 & \pi_3 \\ \pi_1 & \pi_2 & \pi_3 \end{pmatrix}$$

# Lesson 7 : Time in Transient States

> Tips : Inverting a matrix
> $\mathbf{S} = (\mathbf{I} - \mathbf{P}_{\text{transcient}})^{-1}$ , where $s_{ij}$ is the time in state j given that the current state is i.
> $f_{ij} = \frac{s_{ij} - \delta_{i,j}}{s_{jj}} = \sum_{n=1}^{\infty} f_{ij}^{(n)}$, where $f_{ij}$ is the probability that state i ever transitions to state j.

# Lesson 8 : Branching Processes

> A branching process is a special type of Markov chain representing the growth or extinction of a population.
> $\mathrm{E}[X_n] = \mathrm{E}[Z]^n$ , where $\mathrm{E}[Z]$ is the expected number of people born in a generation.
> $\mathrm{Var}(X_n) = \mathrm{Var}(Z) \cdot \mathrm{E}[Z]^{n-1} \sum_{k=1}^{n} \mathrm{E}[Z]^{k-1}$
> If $X_0 \neq 1$ mean and variance of $X_n$ need to be multiplicated by $X_0$.
> **Probability of extinction :**
$$\pi_0 = \sum_{j=1}^{\infty} p_j \pi_0^j$$
> - $\mu \leq 1 \Rightarrow \pi_0 \geq 1$ ,if $X_0 = 1$.
> - $\mu > 1 \Rightarrow \pi_0 < 1$ ,if $X_0 = 1$.

For cubic equation, it guaranteed to factor $(\pi_0 - 1)$. Tips : Synthetic Division

# Lesson 9 : Time Reversible

> If $\mathbf{Q}$ is the reverse-time Markov chain for ergodic $\mathbf{P}$, then
$$\pi_i Q_{ij} = \pi_j P_{ji}$$
with $P_{ii} = Q_{ii}$ and if $p_{ij} = 0 \Leftrightarrow Q_{ji} = 0$
> If $\mathbf{Q} = \mathbf{P}$, then $\mathbf{P}$ is said to be **time-reversible**.

# Lesson 10 : Exponential Distribution

> **Lack of memory :**
$$\Pr(X > k + x | X > k) = \Pr(X > x)$$
> **Minimum :** if $X_i \sim \mathrm{Exp}(\lambda_i)$, then
$$\min(X_1, X_2, ..., X_n) \sim \mathrm{Exp}\left(\sum_{i=1}^{n} \lambda_i\right)$$
> The sum of 2 Exponentials randoms variables is the sum of the maximum and the minimum, since one must be the min and the other the max.
$$X_1 + X_2 = \min(X_1, X_2) + \max(X_1, X_2)$$

# Lesson 11 : Poisson Process

> $X(t) \sim \mathrm{Poisson}[m(t)]$ ,where $m(t)$ is **mean value function** representing the mean of the number events before time $t$.
> Poisson process can't decrease over time. $N(t) \geq N(s) \quad \text{for } t \geq s$
> $N(0) = 0$
> Increament are **independent** :

$$\Pr[N(t) - N(s) = n | N(s) = k] = \Pr[N(t) - N(s) = n]$$
> **Non-homogeneous Poisson process :**
$$m(t) = \int_0^t \lambda(u) \, du$$
where $\lambda(t)$ is the **intensity function**
> **Homogeneous Poisson process :** The Poisson process is said to be homogeneous when the intensity function is a constant.
$$m(t) = \int_0^t \lambda \, du = \lambda t$$
We then say that the process have **stationary increments**.
$$\Pr[N(s - t)] = \Pr[N(t) - N(s)]$$

# Lesson 12 : Poisson Process Time To Next Events

> $T_n$ is the time between the $n^{\text{th}}$ event and the $(n-1)^{\text{th}}$ event.
> $S_n = \sum_{i=1}^{n} T_i$, is the time for the $n^e$ event.
> $F_{T_1}(t) = 1 - e^{-\int_0^t \lambda(u) \, du}$
> For homogeneous process :
$$T_n \sim \mathrm{Exp}(\lambda)$$
$$S_n \sim \mathrm{Gamma}(n, \lambda)$$

# Lesson 13 : Poisson Process Counting Special Type

> If event of type 1 occur with probability $\alpha_1(t)$, then the event follow a Poisson process with intensity $\lambda(t) \cdot \alpha_1(t)$.
$$m(t) = \int_0^t \lambda(u)\alpha_1(u)\,\mathrm{d}u$$

# Lesson 14 : Poisson Process Other Characteristics

> Only for homogeneous Poisson processes.

> The probability of $k$ event from process 1 is given by :
$$k \sim \text{Binomial}\left(k+l-1, \frac{\lambda_1}{\lambda_1 + \lambda_2}\right)$$
Then the probability that $k$ event from process 1 occur before $l$ from process 2 is :
$$\sum_{i=k}^{k+l-1} \binom{k+l-1}{i}\left(\frac{\lambda_1}{\lambda_1+\lambda_2}\right)^i \left(\frac{\lambda_2}{\lambda_1+\lambda_2}\right)^{k+l-1-i}$$

> Given that exactly $N(t) = k$ Poisson events occured before time $t$, the joint distribution of event time is the joint distribution of $k$ independent uniform random variables on $(0, t)$.
$$F_{S_1,\ldots,S_n|n(t)}(s_1,\ldots s_n|k) = \frac{k!}{t^k}$$

> For $k$ independent uniform random variable on $(0, t)$, the expected value of the $j^{\text{th}}$ order statistics is : $E[T^{[j]}] = \frac{jt}{(k+1)}$.

> Tips : Statistic Order

# Lesson 15 : Poisson Process Sums and Mixtures

> A **Sums** of independent Poisson random variables is a Poisson random with intensify function $\lambda(t) = \sum \lambda_i(t)$. Warning : Substraction don't give a Poisson random variable.

> A **Mixture** of Poisson processes is not a Poisson processes.

  – **Discrete** mixture :
  $$F_{X(t)}(t) = \sum_i w_i F_{X_i(t)}(t)$$
  where $w_i > 0, \sum w_i = 1$

  – **Continuous** mixture :
  $$F_{X(t)}(t) = \int F_{\{X_u(t)\}}(t) f(u)\,\mathrm{d}u$$

  – If $N(t)|\lambda$ is a Poisson random variable and $\lambda \sim \text{Gamma}(\alpha,\theta)$, then $N(t) \sim \text{NegBin}(r = \alpha, \beta = \theta t)$.

# Lesson 16 : Compound Poisson Processes

> A **compound** random variable $S$ is define by $S = \sum_{i=1}^N X_i$ where $N$ is the **primary** distribution and $X$ the **secondary** distribution.

> If $N(t)$ is a Poisson process, then $S(t)$ is a compound Poisson process with :
  – $\mathrm{E}[S(t)] = \lambda t \mathrm{E}[X]$
  – $\mathrm{Var}(S(t)) = \lambda t \mathrm{E}[X^2]$

> If $X_i$ is discrete, we can separate the process into a sum of subprocess view in Lesson 13 : Poisson Process Counting Special Type.
> **Sums of compound** homogeneous Poisson process is also a Poisson process with :
  – $N(t) \sim \text{Pois}(\sum \lambda_i)$
  – $F_X(x) = \sum_i w_i F_{X_i(t)}(t), \quad w_i = \frac{\lambda_i}{\sum \lambda_i}$

# Lesson 17 : Reliability Structure Functions

> $\phi(\mathbf{x})$ is the **structure** function for a systeme. It equal 1 if the systeme work, 0 otherwise.

> A **series** system is define as a **minimal path set**. The system is working if all components are working.

The serie structure function is define as
$$\phi(\mathbf{x}) = \prod_{i=1}^n x_i$$

> A **parallel** system is define as a **minimal cut set**. The systeme is working if at least 1 components is working.

The parallel structure function is define as
$$\phi(\mathbf{x}) = 1 - \prod_{i=1}^n (1 - x_i)$$

> Tips : Minimal path set is all way for the system to work, and the minimal cut set is all the way for the system to not work.

> Tips : If set is $\{1,2,3\}$ and $\{1,2\}$, the *minimal* mean we only take $\{1,2\}$.

> Tips : *Minimal cut* is a serie of parallel structure and *minimal path* is a parallel of serie structure.

# Lesson 18 : Reliability Probabilities

> $r(\mathbf{p})$ is the same polynomial as $\phi(\mathbf{x})$.

> Inclusion/exclusion bounds using minimal path :
$$r(\mathbf{p}) \le \sum A_i$$
$$r(\mathbf{p}) \ge \sum A_i - \sum A_i \cup A_j$$
$$r(\mathbf{p}) \le \sum A_i - \sum A_i \cup A_j + \sum A_i \cup A_j \cup A_k$$
where $A_i = \sum p_i$ is the probability of the $i^{\mathrm{e}}$ minimal path set work.

> Inclusion/exclusion bounds using minimal cut :
$$1 - r(\mathbf{p}) \le \sum A_i$$
$$1 - r(\mathbf{p}) \ge \sum A_i - \sum A_i \cup A_j$$
$$1 - r(\mathbf{p}) \le \sum A_i - \sum A_i \cup A_j + \sum A_i \cup A_j \cup A_k$$
where $A_i = \sum(1 - p_i)$ is the probability of the $i^{\mathrm{e}}$ minimal cut set work.

> Bounds using intersections :
$$\prod \phi(\mathbf{X})^{\textbf{min. cut}} \le r(\mathbf{p}) \le \prod \phi(\mathbf{X})^{\textbf{min. path}}$$

> **Random graph** :
$$1 - P_n = \sum_{k=1}^{n-1}\binom{n-1}{k-1} q^{k(n-k)} P_k$$
$$1 - P_n \le (n+1) q^{n-1}$$
$$P_1 = 1$$

# Lesson 19 : Reliability Time to Failure

> Expected amound of time to failure :
$$\mathrm{E}[\textbf{system life}] = \int_0^\infty r(\bar{\mathbf{F}}(\mathbf{t}))\,\mathrm{d}t$$
where,

  – For serie system :
  $$r(\bar{\mathbf{F}}(\mathbf{t})) = \prod_{i=1}^n \bar{F}_i(t)$$

  – For parallel system :
  $$r(\bar{\mathbf{F}}(\mathbf{t})) = 1 - \prod_{i=1}^n F_i(t)$$

> *Shortcut :* $k$ out of $n$ system with exponentials$(\theta)$ : $\mathrm{E}[T] = \theta \sum_{i=k}^n \frac{1}{i}$

> **Hazard rate function** (*failure rate function*) :
$$h(t) = \frac{f(t)}{\bar{F}(t)}$$
and we say that the distribution

  – is an increasing failure rate if $h(t)$ is non-deacreasing function of $t$.

  – is an deacreasing failure rate if $h(t)$ is non-increasing function of $t$.

> **Cumulatice hazard function** :
$$H(t) = \int_0^t h(u)\,\mathrm{d}u = -\ln \bar{F}(t)$$
with $\frac{H(t)}{t}$ the average of the hazard rate.

# Lesson 20 : Survival Models

> $_t p_x = \frac{\ell_{x+t}}{\ell_x}, \quad _t q_x = \frac{\ell_x - \ell_{x+t}}{\ell_x}$

> $_{t|u} q_x = \frac{\ell_{x+t} - \ell_{x+t+u}}{\ell_x}$

> $_{t+u} p_x = {}_u p_x \cdot {}_t p_{x+u}$

> $_{t|u} q_x = {}_{t+u} q_x - {}_t q_x = {}_t p_x \cdot {}_u q_{x+t}$

> Let be $N_x$ the number of life surviving to age $x$, then
$$(N_{x+t}|N_x = n) \sim \text{Bin}(n, {}_t p_x)$$

> **Force of mortality :**
$$\mu_{x+t} = \frac{f_{T_x}(t)}{{}_t p_x} = -\frac{\mathrm{d}}{\mathrm{d}t} \ln {}_t p_x$$

> **Linear interpolation(D.U.D)** :
$$\ell_{x+t} = (1-t)\,\ell_x + t\,\ell_{x+1}$$
Shortcut : $\forall\, t \in (0,1),\ \forall\, x \in \mathbb{N},\ x < x+t < x+1$ :
  - ➡ $_t q_x = t \cdot q_x$
  - ➡ $\mu_{x+t} = \dfrac{q_x}{1 - t \cdot q_x}$

> **Expected life time :** Let $k_x = \lfloor T_x \rfloor$, the *full years* until death. Then $e_x$ is the **curtate life expectancy** and $\mathring{e}_x$ the **complete life expectancy**. $\omega$ is the age where $\ell_\omega = 0$ and $\omega = \infty$ by convention is nothing is said.
$$e_x = \mathrm{E}[K_x] = \sum_{k=1}^{\omega-x-1} {}_k p_x$$
$$\mathring{e}_x = \mathrm{E}[T_x] = \int_0^{\omega-x} {}_t p_x \,\mathrm{d}t \overset{\mathrm{D.U.D}}{=} e_x + 0.5$$

# Lesson 21 : Contingent Payments

The contract here are define with $K_x$ to pay at the end of death year. All same contract can be define with $T_x$ to pay at the moment of death. Then we use integral instead of sum and use
$$\Pr(K = k) = {}_k p_x\, q_{x+k} \Rightarrow f_{T_x}(t) = {}_t p_x \mu_{x+t}$$

> **Life Insurance :**
  - Whole Life insurance :
$$A_x = \sum_{k=0}^{\infty} v^{k+1}\, {}_k p_x\, q_{x+k}$$
  - Term Life insurance :
$$A^1_{x:\overline{n}|} = \sum_{k=0}^{n} v^{k+1}\, {}_k p_x\, q_{x+k}$$
  - Deferred insurance :
$$_{m|}A_x = \sum_{k=m}^{\infty} v^{k+1}\, {}_k p_x\, q_{x+k}$$
  - Endowment insurance :
$$A_{x:\overline{n}|} = A^1_{x:\overline{n}|} + {}_nE_x$$
  - Pure Endowment :
$$_nE_x = v^n\, {}_n p_x$$

> **Life Annuities :**
  - Whole Life annuity
$$\ddot{a}_x = \sum_{k=0}^{\infty} v^k\, {}_k p_x$$
  - Temporary Life annuity
$$\ddot{a}_{x:\overline{n}|} = \sum_{k=0}^{n} v^k\, {}_k p_x$$
  - Deferred annuity
$$_{m|}\ddot{a}_x = \sum_{k=m}^{\infty} v^k\, {}_k p_x$$
  - Certain and life annuity
$$\ddot{a}_{\overline{x:\overline{n}|}} = \ddot{a}_{\overline{n}|} + {}_{m|}\ddot{a}_x$$

> **Illustrative Life Table :**
  - $A_x = v^n q_x + p_x A_{x+1}$
  - $\ddot{a}_x = 1 + v\, p_x\, \ddot{a}_{x+1}$
  - $A^1_{x:\overline{n}|} = A_x - {}_nE_x A_{x+n}$
  - $\ddot{a}_{x:\overline{n}|} = \ddot{a}_x - {}_nE_x \ddot{a}_{x+n}$
  - $_{m|}A_x = {}_mE_x A_{x+m}$
  - $_{m|}\ddot{a}_x = {}_mE_x \ddot{a}_{x+m}$
  - $\ddot{a}_x = 1 + a_x$
  - $A_x = 1 - d\,\ddot{a}_x$

> **Joint life annuity**($\ddot{a}_{xy}$) make payments until the earliest death pf two lives.

> **Last survivor annuity**($\ddot{a}_{\overline{xy}}$) make payments until the last death of two lives.
$$\ddot{a}_x + \ddot{a}_y = \ddot{a}_{xy} + \ddot{a}_{\overline{xy}}$$

> **Premiums :**
$$M \cdot A_x = P\,\ddot{a}_x$$
$$P = \frac{M \cdot A_x}{\ddot{a}_x} = \frac{M}{\ddot{a}_x} - M \cdot d$$

# Lesson 22 : Simulation Inverse Method

> **Linear congruential generators :**
$$x_k = (a x_{k-1} + c) \bmod m$$
$$x_k = b - \left\lfloor \frac{b}{m} \right\rfloor m$$
where $b = (a x_{i-k} + c)$ and $x_0 \equiv$ seed

> **Inverse transformation method :**
$\Pr\left(F^{-1}(u) \le x\right) = \Pr(u \le F(x)) = F(x)$
then $x = F^{-1}(u)$ where $U \sim \mathrm{Unif}(0,1)$
  - Normal Case : $x = \mu + \sigma z$
  - Log-Normal Case : $x = e^{\mu + \sigma z}$
where $z = \Phi^{-1}(u)$, with linear interpolation.

> Tips : Discrete Cumulative Function

> Tips : if $\Uparrow U \equiv\, \Downarrow X$ then $(1 - u_i) \Rightarrow u_i$

# Lesson 23 : Simulation Application

> $\Pr(X \le x) \simeq \dfrac{1}{m} \sum\limits_{j=1}^{m} \mathbb{1}_{\{x^{(j)} \le x\}}$

> $\mathrm{E}[X^k] \simeq \dfrac{1}{m} \sum\limits_{j=1}^{m} [x^{(j)}]^k$

> $\mathrm{VaR}_k(X) \simeq X^{[j_0]}$

> $\mathrm{TVaR}_k(X) \simeq \dfrac{1}{m(1-k)} \sum\limits_{j=j_0+1}^{m} X^{(j)} \mathbb{1}_{\{X^{(j)} > X^{[j_0]}\}}$
$$\simeq \frac{1}{m - j_0} \sum_{j=j_0+1}^{m} X^{[j]}$$
where
  - $j_0 = \lfloor m \cdot k \rfloor$
  - $m$ is the number of simulations.
  - $X^{(j)}$ is the jᵗʰ simulations.
  - $X^{[j]}$ is the jᵗʰ simulations in order statistics.

# Lesson 24 : Simulation Rejection Method

> **General method :** Let $f(x)$ be the density function of variable to simulate, and let $g(x)$ be the **base distribution**, a random density function that is easy-to-simulate with nonzero wherever $f(x) \ne 0$.
$$c = \max \frac{f(x)}{g(x)}$$

Generate two uniform number $u_1, u_2$. Let $x_1 = G^{-1}(u_1)$. Accept $x_1$ only if
$$u_2 \le \frac{f(x_1)}{c \cdot g(x_1)}$$

> **Simulating gamma distribution :** Use $\mathrm{Exp}(\alpha \cdot \theta)$ as the base distribution and $x = \alpha \cdot \theta$ that maximize $c$.

> **Simulating standard normal distribution :** Generate 3 uniform $u_1, u_2, u_3$. Let $y_1 = -\ln u_2$ and $y_2 = -\ln u_2$. Accept $y_1$ if
$$y_2 \ge \frac{(y_1 - 1)^2}{2}$$
and add $(-)$ if $u_3 \ge 0.5$

> The **Number of iteration** is a Ross-geometric distribution with mean c. Let be $\beta$ the mean of a geometric distribution given in the exam appendix :
$$\mathrm{E}[N] = 1 + \beta = c$$
$$\mathrm{Var}(N) = \beta(1 + \beta)$$

# Lesson 25 : Estimator Quality

> **Bias :** This quality measures if, on average, the estimator is on the expected value of the parameter.
$$\mathrm{E}[\hat\theta] = \theta + \mathrm{bias}_{\hat\theta}(\theta)$$
  - If $\mathrm{bias}_{\hat\theta}(\theta) = 0$, then $\hat\theta$ is **unbiased**.
  - If $\lim\limits_{n\to\infty} \mathrm{bias}_{\hat\theta}(\theta) = 0$, then $\hat\theta$ is **asymptotically unbiased**.
  - If $\mathrm{bias}_{\hat\theta}(\theta) \ne 0$, then $\hat\theta$ is **biased**.

> **Consistency :** This quality measures if the probability that the estimator is different from the parameter by more than $\varepsilon$ goes to 0 as $n$ goes to infinity.
$$\lim_{n\to\infty} \Pr(|\hat\theta - \theta| > \varepsilon) \to 0,\ \forall \varepsilon > 0$$
In other word, as $n \to \infty$, $\mathrm{E}[\hat\theta] \to \theta$, $\mathrm{Var}(\hat\theta) \to 0$

> **Efficiency :** This quality measures the variance of the estimator. Lower the variance is, more efficient is the estimator.
$$\text{Efficiency of } \hat\theta = \frac{\mathrm{Var}(\hat\theta)^{\mathrm{rao}}}{\mathrm{Var}(\hat\theta)}$$
$$\text{Relative efficiency of } \hat\theta_1 \text{ to } \hat\theta_2 = \frac{\mathrm{Var}(\hat\theta_2)}{\mathrm{Var}(\hat\theta_1)}$$
See the rao-cramer lower bound.

> **Mean Square Error :** This quality measures the expected value of the square difference between the estimator and the parameter.
$$\mathrm{MSE}_{\hat\theta}(\theta) = \mathrm{E}\left[(\hat\theta - \theta)^2\right] = \left(\mathrm{bias}_{\hat\theta}(\theta)\right)^2 + \mathrm{Var}(\hat\theta)$$

> An estimator is called a **uniformly minimum variance unbiased estimator(UMVUE)** if it's unbiased and if there is no other unbiased estimator with a smaller variance for any true value $\theta$.

> Some estimator :
  - $\bar x = \frac{1}{n} \sum x_i$ is a unbiased estimator of the mean $\mu$. $\mathrm{Var}(\bar x) = \frac{1}{n}\mathrm{Var}(x)$

– $s^2 = \sum \frac{(x_i - \bar{x})^2}{n-1}$ is a unbiased estimator of the variance $\sigma^2$.

– $\hat{\sigma}^2 = \sum \frac{(x_i - \bar{x})^2}{n}$ is an asymptotically unbiased of the variance $\sigma^2$.

– $\hat{\mu}'_k = \frac{1}{n} \sum x_i^k$, where $\hat{\mu}'_1 = \bar{x}$ and $\hat{\mu}_k = \frac{1}{n} \sum (x_i - \bar{x})^k$, where $\hat{\mu}_1 = 0$ and $\hat{\mu}_2 = \hat{\sigma}^2$.

# Lesson 26 : Kernel Density Estimation

> **Empirical distribution :** All data is assigning a probability of $\frac{1}{n}$. This is the same method used for simulation, see Lesson 23 : Simulation Application.

$$F_e(x) = \frac{1}{n} \sum_{i=1}^{n} \mathbb{1}_{\{x_i \le x\}}$$

$$f_e(x) = \frac{1}{n} \sum_{i=1}^{n} \mathbb{1}_{\{x_i = x\}}$$

$$= F_e(x) - F_e(x_{i-1})$$

> **Kernel Density** is a empirical distribution smoothed with a base fonction. Let define the scaling factor $b$ called **bandwith**.

– The kernel-density estimate of the density function is : $\hat{f}(x) = \frac{1}{n} \sum k\left(\frac{x - x_i}{b}\right)$

$$\Leftrightarrow \sum f_e(x) k\left(\frac{x - x_i}{b}\right)$$

– The kernel-density estimate of the distribution is : $\hat{F}(x) = \frac{1}{n} \sum K\left(\frac{x - x_i}{b}\right)$

> **Rectangular(uniform, box) kernel :**

$$k(x) = \begin{cases} \frac{1}{2b}, & -1 \le x \le 1 \\ 0, & \text{otherwise} \end{cases}$$

$$K(x) = \begin{cases} 0, & x < -1 \\ 0.5(x+1), & -1 \le x \le 1 \\ 1, & x > 1 \end{cases}$$

$$\hat{f}(x) = \frac{F_e(x+b) - F_e(x - b^-)}{2b}$$

> **Triangular kernel :**

$$k(x) = \begin{cases} \frac{1 - |x|}{b}, & -1 \le x \le 1 \\ 0, & \text{otherwise} \end{cases}$$

$$K(x) = \begin{cases} 0, & x < -1 \\ \frac{(1+x)^2}{2}, & -1 \le x \le 0 \\ 1 - \frac{(1-x)^2}{2}, & 0 \le x \le 1 \\ 1, & x > 1 \end{cases}$$

> **Gaussian kernel :** The distribution become normal with $\mu = x_i$ and $\sigma = b$.

$$k(x) = \frac{e^{-x^2/2}}{b\sqrt{2\pi}}$$

$$K(x) = \Phi(x)$$

> Other kernel : $k(x) = \beta(x)$ and $k(x) = B(x)$

> **kernel moments :** Let $X$ be the kernel density estimate and $x_i$ the empirical estimate.

We then condition on $x_i$.

$$\mathrm{E}[X] = \mathrm{E}\big[\mathrm{E}[X|x_i]\big] = \mathrm{E}[x_i]$$

$$\mathrm{Var}(X_R) = \mathrm{Var}(x_i) + \frac{b^2}{3}$$

$$\mathrm{Var}(X_T) = \mathrm{Var}(x_i) + \frac{b^2}{6}$$

$$\mathrm{Var}(X_G) = \mathrm{Var}(x_i) + b^2$$

> Tips : For rectangular kernel, $\mathrm{E}[x|x_i]$ is a uniform$(x_i - b, x_i + b)$.

# Lesson 27 : Method of Moments

> **Types of data :**

– Complete data : Data is complete if we are given the exact value of each observation.

– Grouped data : Set of interval and we know how many observation are in each.

– Censored data : Value that are in a interval, but we don't know the exact value. Like limits $(\min(X, u))$.

– Truncated data : We have data only when it in certain range, otherwise we don't know. Like deductible $(X|X > d)$.

> **Method of Moments :** We match $\hat{\mu}'_k = \mathrm{E}\big[X^k\big]$ and find the parameters. If data is Censored or Truncated, we need to match the censored or truncated moment : $\hat{\mu}'_k = \mathrm{E}\big[\min(X, u)^k\big]$ or $\hat{\mu}'_k = \mathrm{E}\big[X^k|X > d\big]$.

> For pareto distribution, if $\hat{\mu}'_2 = \hat{\sigma}^2 + \bar{x}^2 \le 2\bar{x}^2$, the method of moment is unstable and can't be used.

# Lesson 28 : Percentile Matching

> **Percentile Matching :** We match $F_e(\hat{\pi}_p) = p$ and find the parameters.

– For censored data, we need select percentiles within the range of the uncensored portion of the data.

– For truncated data, we need to match the percentiles of the conditional distribution :
$$F(x|X > d) = \frac{\Pr(d < X \le x)}{\Pr(X > d)} = \frac{F(x) - F(d)}{1 - F(d)}$$
$$S(x|X > d) = \frac{S(x)}{S(d)}$$

> **Smoothed empirical percentile :**
$$\hat{\pi}_p = (1 - h) X^{[j]} + h X^{[j+1]}$$
where

– $j = \lfloor (n+1)p \rfloor$

– $h = (n+1)p - j$

– $X^{[j]}$ is the j$^{\text{th}}$ order statistics.

# Lesson 29 : Maximum Likehood Estimators

> **Maximum Likehood Estimators :** We maximize the probability of observing the data.
$$L(\theta) = \prod g(x_i; \theta)$$
$$l(\theta) = \sum \ln g(x_i; \theta)$$

– Individual data : $g(x_i; \theta) = f(x_i)$

– Grouped data : $g(x_i; \theta) = F(x_i) - F(x_{i-1})$

– Censored data : $g(x_i; \theta) = S(x_i)$

– Truncated data : $g(x_i; \theta) = \frac{f(x)}{s(x)}$

# Lesson 30 : MLE Special Techniques

> Case MLE equals MME

– For Exponential, $\hat{\theta}^{\text{MLE}} = \bar{x}$

– For Gamma with fixed $\alpha$, $\hat{\theta}^{\text{MLE}} = \hat{\theta}^{\text{MME}}$

– For Normal, $\hat{\mu}^{\text{MLE}} = \bar{x}$ and $(\hat{\sigma}^2)^{\text{MLE}} = \frac{1}{n} \sum (x_i - \hat{\mu})^2$

– For Binomial, $mq = \bar{x}$ then given $m$, $\hat{q}^{\text{MLE}} = \frac{\bar{x}}{m}$

– For Poisson, $\hat{\lambda}^{\text{MLE}} = \hat{\lambda}^{\text{MME}}$

– For Binomial Negative, given $r$ or $\beta$, $(r\beta)^{\text{MLE}} = \bar{x}$

> Parametrization and Shifting :

– Parametrization : MLE's are independent of parametrization
$$\lambda = \frac{1}{\theta} \Leftrightarrow \hat{\lambda}^{\text{MLE}} = \frac{1}{\hat{\theta}^{\text{MLE}}}$$

– Shifting the distribution is equivalent of shifting the data.

> Transformations : MLE's are invariant under one-to-one transformation. Then if we have a transformed variable, we can untransform the data and find the parameter of the untransform distribution.
Tips : Transformations of distribution

> Weibull distribution : If the data is censored(u) or truncated(d), then
$$\left(\hat{\theta}^{\text{MLE}}\right)^\tau = \frac{\sum x_i^\tau - \sum d_i^\tau}{\sum \mathbb{1}_{\{x_i \le u\}}}$$
if $\tau = 1$, then the distribution is Exponential.

> Pareto distribution with fixed $\theta$ : $\hat{\alpha} = -\frac{n}{K}$
$$K = \sum_{i=1}^{n+c} \ln(\theta + d_i) - \sum_{i=1}^{n+c} \ln(\theta + x_i)$$
where $n \equiv$ number of non-censored(c) data.

> Single-parameter Pareto : $\hat{\alpha} = -\frac{n}{K}$
$$K = \sum_{i=1}^{n+c} \ln \max(\theta, d_i) - \sum_{i=1}^{n+c} \ln x_i$$
where $n \equiv$ number of non-censored(c) data.

> Uniform$(0, \theta)$ : We take the smalest $\theta$ possible, $\hat{\theta}^{\text{MLE}} = \max(x_1, ..., x_n)$

– Censored(u) : $\hat{\theta}^{\text{MLE}} = \frac{nd}{\sum \mathbb{1}_{\{x_i < d\}}}$

– Grouped : We take the heighest interval(L, U). $\hat{\theta}^{\text{MLE}} = \min(U, \hat{\theta}^{\text{MLE}}_{\text{Censored(L)}})$

> Bernouilli : Let have a random variable that can take 2 values, $n$ and $m$. Then
$$\hat{p} = \frac{n}{n+m}$$

> Tips : If $L(\theta)$ look like a density distribution, $\hat{\theta}^{\text{MLE}} \equiv$ mode of this distribution.

> **Ground-up loss** is define as (x|x>d).

# Lesson 31 : Variance of MLE

> **Fisher information matrix** :
$$I(\theta) = n\mathrm{E}\left[\left(\frac{\mathrm{d}\ln f(x;\theta)}{\mathrm{d}\theta}\right)^2\right]$$
$$= -n\mathrm{E}\left[\frac{\mathrm{d}^2\ln f(x;\theta)}{\mathrm{d}\theta^2}\right]$$
using the loglikelihood function
$$I(\theta) = \mathrm{E}\left[\left(\frac{\mathrm{d}l(x_1,...,x_n;\theta)}{\mathrm{d}\theta}\right)^2\right]$$
$$= -\mathrm{E}\left[\frac{\mathrm{d}^2 l(x_1,...,x_n;\theta)}{\mathrm{d}\theta^2}\right]$$

> **Rao-Cramer lower bound** is the lowest possible variance for a unbiased estimator $\hat{\theta}$ of $\theta$. Then $\hat{\theta} \sim \text{Normal}(0, \text{Var}(\hat{\theta})^{\text{rao}})$
$$\text{Var}(\hat{\theta})^{\text{rao}} \geq \frac{1}{I(\theta)}$$
under certains regularity conditions

– The seconde derivative of the loglikehood exist.

– The support of the density function is not function of $\theta$.

# Lesson 32 : Sufficient Statistics

> A **sufficient statistics** are statistics that capture all the information about the parameter we are estimating that the sample as to offer.

> A statistics is sufficient when the distribution of a sample given a statistics does not depend on the parameter. $Y$ is a sufficient statistics for a parameter $\theta$ if and only if
$$L(x_1,...,x_n;\theta|Y) = h(x_1,...,x_n)$$
$$L(x_1,...,x_n;\theta) = g(y)h(x_1,...,x_n)$$
where $h(x_1,...,x_n)$ is a function that does not involve $\theta$.

> **Rao-Blackwell** Theorem : For any unbiased estimator $\hat{\theta}$ and sufficient statistic $Y$, the estimator $\mathrm{E}[\hat{\theta}|Y]$ is unbiased and has variance less than or equal to $\text{Var}(\hat{\theta})$.

> The maximum likehood estimator is a function of a sufficient statistic.

# Lesson 33 : Hypothesis Testing

> Let be $H_0$ the **null hypothesis** and $H_1$ the **alternative hypothesis**.

|           | Accept $H_0$ | Reject $H_0$ |
|-----------|:------------:|:------------:|
| $H_0$ True | $1 - \alpha$ | $\alpha$ |
| $H_1$ True | $\beta$ | $1 - \beta$ |

> The $\alpha$ value is usuly name :

– Probability of Type I error

– Size of critical region

– signifiance level

The $\beta$ value is usuly name :

– Probability of Type II error

The $(1 - \beta)$ value is usuly name :

– The power of test.

> We will reject $H_0$ in favor of $H_1$ if a certain condition occured ($X > \gamma$), named the **critical region**. Then the probability of rejecting $H_0$ is giving by
$$\Pr(X > \gamma | H_0 \equiv \text{true}) = \alpha$$

> Lowering the probability of type I error came at the cost of raising the probability of type II error. One way to lower both is to increase sample size.

> The **p-value** is the probability of being greater or equal to the observation if $H_0$ is true. $H_0$ is rejected if and only if the p-value is less then the signifiance level.
$$P_{\text{value}} < \alpha$$

# Lesson 34 : Confidence Interval and Sample Size

> Let be $c$ the **confidence coefficient**. Then we can say the we're $100c\%$ confident that the parameter is between $(a, b)$, called the **confidence interval**. $\alpha = 1 - c$
$$\theta \in \hat{\theta} \pm z_{\frac{1+c}{2}} \sqrt{\text{Var}(\hat{\theta})}$$

> We can found the probability that the half-width of the interval is less then $k$.
$$\Pr(|\hat{\theta} - \theta| \leq k) \geq \frac{1+c}{2}$$
$$\Phi\left(\frac{k}{\sqrt{\sigma^2/n}}\right) \geq \frac{1+c}{2}$$

> To find the sample size needed to have a certain ($\alpha$) and ($1 - \beta$), we resolve
$$\Pr(\bar{x} > k | H_0) = 1 - \Phi\left(\frac{k - \mu_0}{\sqrt{\sigma^2/n}}\right) = \alpha$$
$$\Pr(\bar{x} > k | H_1) = 1 - \Phi\left(\frac{k - \mu_1}{\sqrt{\sigma^2/n}}\right) = 1 - \beta$$

# Lesson 35 : Confidence Intervals for Means

> The **chi-sqare** is a one-parameter family distribution. In definition, it a gamma with $\alpha = \frac{n}{2}$ and $\theta = 2$. The only parameter $n$ is called **degree of freedom**.

– Let $X_i, i = i,...,n$ be normal random variable with mean $\mu$ and varianve $\sigma^2$.
$$Y = \sum_{i=1}^{n} \frac{(X_i - \mu)^2}{\sigma^2} \sim \chi^2_{(n)}$$

– Let $x_i, i = i,...,n, n \geq 2$ be random sample from normal distribution with variance $\sigma^2$.
$$W = \sum_{i=1}^{n} \frac{(x_i - \bar{x})^2}{\sigma^2} \sim \chi^2_{(n-1)}$$

– Tips : $\chi^2_{(2)} \sim \text{Exp}(\theta = 2)$

> The **strudent** is a one-parameter family distribution. We define it as
$$T_{(n)} = \frac{Z}{\sqrt{W/n}}$$
where $Z \sim \text{N}(0, 1)$ and $W \sim \chi^2_{(n)}$.
Note that as $n \to \infty$, $T_{(n)} \to N(0, 1)$

> When the variance is unknow, we need to estimate it with the unbiased estimator $S^2$.
$$T_{(n-1)} = \frac{\bar{x} - \mu}{\sqrt{S^2/n}}$$

> Testing the difference of means from two population.
$$x_1,...,x_n \sim N(\mu_x, \sigma_x^2)$$
$$y_1,...,y_m \sim N(\mu_y, \sigma_y^2)$$
$$T_{(n+m-2)} = \frac{(\bar{x} + \bar{y}) - (\mu_x - \mu_y)}{S\sqrt{\frac{1}{n} + \frac{1}{m}}}$$
where $S^2 = \frac{(n-1)S_x^2 + (m-1)S_y^2}{m+n-2}$.

> Testing for mean of bernouilli population. Let $p_0$ the probability on $H_0$.
$$Z = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1-p_0)}{n}}}$$

# Lesson 36 : Kolmogorov-Smirnov Tests

> The **Kolmogorov-Smirnov test** is one methode for determining how well a parametric model fits its data. This test is only appropriate for continuous distribution.
$$D = \max|F_e(x) - F^*(x;\hat{\theta})|$$

where $d \le x \le u$ and $F^*(x) = \frac{F(x)-F(u)}{S(d)}$.

| $x_i$ | $F^*(x_i)$ | $F_e(x_i^-)$ | $F_e(x_i)$ | max |
|-------|-----------|-------------|-----------|-----|
| $x_1$ | 0.5 | 0.2 | 0.6 | 0.3 |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |

# Lesson 37 : Chi Square Test

> The **Chi Square** look for equality of means between $k$ group. Let $O_i$ be the observation and $E_i = np_i$ the expected on each group.
$$H_0 : \mu_1 = ... = \mu_k$$

$$Q = \sum_{i=1}^{k} \frac{(O_i - E_i)^2}{E_i} = \sum_{i=1}^{k} \left( \frac{O_i^2}{E_i} \right) - n \sim \chi^2_{(k-1-\theta')}$$

Note : This test can be use to test the fit of as parametric model. $\theta'$ is the number of parameter fited with the same data as the test.

> **Two-dimensional chi-square :**
$$Q = \sum_{i=1}^{k} \sum_{j=1}^{c} \frac{(O_{ij} - E_{ij})^2}{E_{ij}} \sim \chi^2_{(k-1)(c-1)}$$

# Lesson 38 : Confience Interval for Variances

> To find a confidence interval for the variance, we need the following statistic.
$$W = \frac{(n-1)S^2}{\sigma^2} \sim \chi^2_{(n-1)}$$

> Warning : $W$ is on the denominator, so for upper one-sided interval, we take the lower percentile $\alpha$ and $1 - \alpha$ for lower one-sided interval.

1. $\left( 0, \frac{(n-1)S^2}{w_\alpha} \right)$

2. $\left( \frac{(n-1)S^2}{w_{1-\alpha}}, \infty \right)$

3. $\left( \frac{(n-1)S^2}{w_{1-\frac{\alpha}{2}}}, \frac{(n-1)S^2}{w_{\frac{\alpha}{2}}} \right)$

> The **Fisher** distribution is define as
$$F_{(r_1, r_2)} = \frac{W_1/r_1}{W_2/r_2}$$

where $r_1$ and $r_2$ are the degree of freedom.

> If $T \sim$ Strudent, then $T^2 \sim$ Fisher.

> To find a confidence interval for variance ratio, we need the following statistic.
$$F_{(n_x-1, n_y-1)} = \frac{S_x^2/\sigma_x^2}{S_y^2/\sigma_y^2}$$

# Lesson 39 : Uniformly Most Powerful critical Regions

> The **Neyman-Pearson lemma** states that for tests of one *simple* hypothesis against another, the best critical region for any $(\alpha)$ is to select all that minimize the likelihood ratio.
$$h(x) = \frac{L(x_1, ..., x_n; \theta | H_0)}{L(x_1, ..., x_n; \theta | H_1)} < c$$

  − If $h(x)$ is increasing, $F(k | H_0) < \alpha$.

  − If $h(x)$ is deacreasing, $S(k | H_0) < \alpha$.

> If the alternative hypothesis is *composite*, then we can find the **uniformly most powerful critical region** with the same likehood ratio. This region only exist for one-sided test.

# Lesson 40 : Likehood Ratio Tests

> This test is usefull when there is no uniformly most powerful critical region.
$$h(x) = \frac{g(x_1, ..., x_n; \theta | H_0)}{g(x_1, ..., x_n; \theta | H_1)}$$

where $g(x_1, ..., x_n; \theta)$ is the maximum likehood.

> For large sample, we can use the asymptotic distribution of the likelihood.
$$-2[l(\theta | H_0) - l(\theta | H_1)] \sim \chi^2_{(k-l)}$$

where $k$ is the number of parameters specifies by $H_0$ and $l$ is the combinaison of numbers of parameters specifies by $H_0$ and $H_1$.

> The last test can also be use to dicide if it worth to add parameter to a distribution fit.

# Lesson 41 : q-q Plots

> This plot compare quantile of two distribution. It consiste of a plot of coordinate pairs : $\left( \mathbf{x_i}, F^{-1}(\mathbf{p_i}) \right)$ where $p_i$ is the empirical percentile of $x_i$. Then the fit is good if the point are close to a $45°$ line.

# Lesson 42 : Introduction to Extended Linear Models

There are two purposes in building a extended linear model.

1. **Prediction :** We want to predic the valu of the *response* variable given specific values of the *explanatory* variables.

2. **Inference :** We want to understand which *explanatory* variables explain the *response* variable and how much their explain it.

To evaluate the accuracy of a model, we estimate it mean square error.
$$\text{MSE} = \frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i)$$

# Lesson 43 : How a Generalized Linear Model Works

> **Linear Model :**
$$Y = \eta + \varepsilon = \beta_0 + \beta_1 x_1 + ... + \beta_p x_p + \varepsilon$$

where
$$\varepsilon \sim N(0, \sigma^2)$$
$$Y \sim N(\eta, \sigma^2)$$

**Hypothesis** :

($\mathbf{H_1}$) $\text{E}[\varepsilon] = 0$        (Linearity)

($\mathbf{H_2}$) $\text{Var}(\varepsilon) = \sigma^2$    (Homoscedasticity)

($\mathbf{H_3}$) $\text{Cov}(\varepsilon_i, \varepsilon_j) = 0$  (Independence)

> The **Box-Cox transformation** is a general set of transformation. When the variance of the error terms is not constant($H_2$), we need to transforme $Y$.
$$Y^* = \begin{cases} \frac{Y^\lambda - 1}{\lambda} & \lambda \ne 0 \\ \ln Y & \lambda = 0 \end{cases}$$

where $\lambda$ is chossen to best stabilize the variance of the error terms.

> The *feature* must be linearly independent. That mean their can't be a function of another. Ex : $X_3 = 1 - X_2$.

> We need to encode categorials variables with $k$ levels into $(k-1)$ indicators variables(called *dummy* variables) to avoid *feature* to be dependent. For interaction with 2 categorials variables, $(k-1)(l-1)$ dummy variables are needed.

> **GLM :**
$$g(\text{E}[Y]) = \beta_0 + \sum_{i=1}^{n} \beta_i x_i$$

where $g(\cdot)$ is the link function.

> **Exponential Family :**
$$f(y; \theta) = \exp\{a(y)b(\theta) + c(\theta) + d(y)\}$$

with
$$\text{E}[a(y)] = -\frac{c'(\theta)}{b'(\theta)}$$
$$\text{Var}(a(y)) = \frac{b''(\theta)c'(\theta) - c''(\theta)b'(\theta)}{[b'(\theta)]^3}$$

> **Tweedie** distribution :
$$\text{Var}(Y) = a\text{E}[y]^p$$

> **link function :** The GLM estimate is unbiased when the canonical link is used.

| Distribution | Canonical link |
|-------------|---------------|
| Normal | $g(y) = y$ |
| Binomial | $g(y) = \ln \frac{y}{1-y}$ |
| Poisson | $g(y) = \ln y$ |
| Gamma | $g(y) = \frac{1}{y}$ |

> **Offset :** We add $\ln n_i$ for cell with $n_i$ exposure.

> **Rate ratio :**
$$RR = \frac{\text{E}[Y_i | x_j = 1]}{\text{E}[Y_i | x_j = 0]}$$

# Lesson 44 : Categorial Response

## Binomial Response

> Let $\pi_i \in (0,1)$ be the response variable. We than need to have link that map $\eta$ into $(0,1)$.

> - **logit :** $\ln\left(\frac{\pi}{1-\pi}\right) = \eta$

> - **Probit :** $\Phi^{-1}(\pi) = \eta$

> - **Log-log :** $\ln(-\ln(1-\pi)) = \eta$

> **Odds Ratio :** $o = \frac{\pi}{1-\pi}$

## Nominal Response

> Suppose the response can be $J$ values. Then we create a model of relative odds.
$$\ln\frac{\pi_j}{\pi_1} = \eta_j \Leftrightarrow \pi_j = \pi_1 e^{\eta_j}$$

> - $\pi_i = \frac{1}{1+\sum_{j=2}^{J} e^{\eta_j}}$

> - $\pi_j = \frac{e^{\eta_j}}{1+\sum_{j=2}^{J} e^{\eta_j}}$

> If $x_i$ is a binary feature, then the odds ratio of this **variable** in the category $j$ to the base categorie is $e^{\beta_{ij}}$.

## Ordinal Response

Ordinal response variables have several categories in logical order.

> **Cumulative logit and proportional odds models :**
$$\ln o_j = \ln\frac{\sum_{k=1}^{j} \pi_k}{1 - \sum_{k=1}^{j} \pi_k} = \eta_j$$
Tips : The model is cumulative, so to find $\pi_2$, we need to find $\pi_1$ and $\pi_1 + \pi_2$.
This model is proportional so if we **fix** the categorie but consider two set of feature $x_{i1}$ and $x_{i2}$, the relative odds are
$$\frac{(o_j|x_i=x_{i1})}{(o_j|x_i=x_{i2})} = e^{\sum \beta_i(x_{i1}-x_{i2})}$$

> **Adjacent categorie logit model :**
$$\ln\frac{\pi_j}{\pi_{j+1}} = \eta_j$$
$$\sum_{j=1}^{J} \pi_j = 1$$

> **Continuation ratio logit model :**
$$\ln\frac{\pi_j}{\sum_{k=j+1}^{J} \pi_k} = \ln\frac{\pi_j}{1-\sum_{k=1}^{j}\pi_k} = \eta_j$$
Tips : Resolve for $\pi_1$ then for $\pi_2$ and so on ...

# Lesson 45 : Estimating Parameters

> Let $\mathbf{X}$ be the **design matrix**, the p x n features matrix.

> **Linear Regression :**
$$\hat{\beta}_1 = \frac{\sum x_i y_i - n\bar{x}\bar{y}}{\sum x_i^2 - n\bar{x}^2}$$
$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1\bar{x}$$
$$\mathbf{b} = (\mathbf{X}^\mathsf{T}\mathbf{X})^{-1}\mathbf{X}^\mathsf{T}\mathbf{y}$$

> The **score** function is define as the derivative of the loglikehood
$$\mathbf{U}(\beta) = \ell'(\beta)$$

> **Newton-Raphson** algorithm :
$$\beta^{(k+1)} = \beta^{(k)} - \frac{\mathbf{U}(\beta^{(k)})}{\mathbf{U}'(\beta^{(k)})}$$

> **Fisher Scoring** algorithm :
$$\beta^{(k+1)} = \beta^{(k)} - \frac{\mathbf{U}(\beta^{(k)})}{\mathrm{E}[\mathbf{U}'(\beta^{(k)})]}$$

> The score vector has components
$$U_j = \sum_{i=1}^{n} \frac{y_i - \mu_i}{\mathrm{Var}(y_i)} x_{ij}\left(\frac{\mathrm{d}g(\mu_i)}{\mathrm{d}\mu_i}\right)$$

> The information matrix : $I(\theta) = \mathbf{X}^\mathsf{T}\mathbf{W}\mathbf{X}$

> Let $\mathbf{W}$ be the diagonal matrix with entries
$$w_{ii} = \left(\left(\frac{\mathrm{d}g(\mu_i)}{\mathrm{d}\mu_i}\right)^2 \mathrm{Var}(y_i)\right)^{-1}$$

> Let $\mathbf{G}$ be the diagonal matrix with entries
$$G_{ii} = \frac{g(\mu_i)}{\mu_i}$$

> The regression variable for one iteration
$$\mathbf{z}^{(k-1)} = \mathbf{X}\mathbf{b}^{(k-1)} + \mathbf{G}^{(k-1)}(\mathbf{y} - \mu^{(k-1)})$$

> The **Weighted Least Square** :
$$\mathbf{b}^{(k)} = (\mathbf{X}^\mathsf{T}\mathbf{W}^{(k-1)}\mathbf{X})^{-1}\mathbf{X}^\mathsf{T}\mathbf{W}^{(k-1)}\mathbf{z}^{(k-1)}$$

# Lesson 46 : Measures of Fit

> The **satured** model is when we have as much feature as parameters($p = n$). $g^{-1}(\mathbf{X}^\mathsf{T}\mathbf{b}) = \mathbf{y}$

> The **deviance** statistic test compare a model to the satured model.
$$D = 2[\ell(\mathbf{b}_{max}) - \ell(\mathbf{b})] \approx n - p'$$
where $p' = p + 1$ and $p$ the number of feature.

> - Binomial :
$$D = 2\sum_{i=1}^{n}\left(y_i \ln\frac{y_i}{\hat{y}_i} + (n_i - y_i)\ln\frac{n_i-y_i}{n_i-\hat{y}_i}\right)$$

> - Normal (*scaled deviance*) :
$$\sigma^2 D = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2$$

> - Poisson :
$$D = 2\sum_{i=1}^{n}\left(y_i \ln\frac{y_i}{\hat{y}_i} - (y_i - \hat{y}_i)\right)$$

> - Gamma :
$$D = 2\alpha\sum_{i=1}^{n}\left(-\ln\frac{y_i}{\hat{y}_i} + \frac{y_i-\hat{y}_i}{\hat{y}_i}\right)$$

## Signifiance of Feature

> **Loglikelihood ratio test :** These tests compare a **unconstrained** modele with $p + q$ parameters versus another **constrained** model with $p$ parameters.
$$2(\tilde{\ell}_{p+q} - \hat{\ell}_p) \sim \chi^2_{(q)}$$
$$\hat{D} - \tilde{D} \sim \chi^2_{(1)}$$

> **Wald test :** To test wheter a single parameter $\beta_j = r$.
$$W = \frac{(\hat{\beta}_j - r)^2}{\mathrm{Var}(\hat{\beta}_j)} \sim \chi^2_{(1)}$$

$\sqrt{W} \sim N(0,1)$, is usefull for confidence interval.

$I(\theta)^{-1} = (\mathbf{X}^\mathsf{T}\mathbf{W}\mathbf{X})^{-1}$ is the covariance matrix.

> **Score text :** $\mathbf{U}^\mathsf{T} I(\theta)^{-1}\mathbf{U} \sim \chi^2_{(q)}$

If $q = 1$, $\frac{U}{\sqrt{I(\theta)}} \sim N(0,1)$.

> We want the lowest AIC and BIC.

# Lesson 47 : Standard Error, $R^2$, and Strudent Statistic

$$SST = SSE + SSR$$

> **Total sum of square :** $SST = \sum_{i=1}^{n}(y_i - \bar{y})^2$

> **Error sum of square :** $SSE = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2$
$$SSE = \varepsilon^\mathsf{T}\varepsilon = \mathbf{y}^\mathsf{T}\mathbf{y} - \mathbf{b}^\mathsf{T}\mathbf{x}^\mathsf{T}\mathbf{y}$$

> **Regression sum of square :** $SSR = \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2$

| ANOVA | | | |
|-----|------|-------------|------|
| SS | df | MS | F |
| SSR | p | MSR = SSR/df | $\frac{MSR}{MSE}$ |
| SSE | n-p' | MSE = SSE/df | |
| SST | n-1 | MST = SST/df | |

> The standort error of the regression is
$$s = \sqrt{MSE}$$

> The **coefficient of determination** is the proportion explain by the regression.
$$R^2 = \frac{SSR}{SST} = 1 - \frac{SSE}{SST}$$

> **Strudent test :** To test $\beta_i = \beta^*$
$$t_{n-p'} = \frac{\beta_i - \beta^*}{S_{\beta_i}}$$

Matrice variance-covariance : $\sigma^2(\mathbf{X}^\mathsf{T}\mathbf{X})^{-1}$

> Simple linear regression :

> - $\mathrm{Var}(\hat{\beta}_0) = \sigma^2\left(\frac{1}{n} + \frac{\bar{x}^2}{S_{xx}}\right)$

> - $\mathrm{Var}(\hat{\beta}_1) = \frac{\sigma^2}{S_{xx}}$

> - $\mathrm{Cov}(\hat{\beta}_0, \hat{\beta}_1) = -\frac{\bar{x}\sigma^2}{S_{xx}}$

# Lesson 48 : Fisher Statistic and VIF

› The **Fisher** statistic test the signifiance od the entire regression, in other word if all $\beta_i = 0$. For simple linear regression $F = T^2$. Tips : Divide numerator and denominator of $F$ by SST to find $R^2$.

› For simple linear regression, since $p = 1$, then
$$T_{(n)} = \sqrt{F_{1,n}}.$$

› **Partial Fisher test :** To test is $q$ added variables have signifiance.
$$F_{\Delta_{df}, n-p'} = \frac{SSE^{(0)} - SSE^{(1)} / \Delta_{df}}{SSE^{(1)} / (n-p')}$$

› The **Variance Inflation Factor** test the collinearity of the features. To mesure it, we take the $x_j$ feature and take it as the response. Let $R^2_{(j)}$ be the $R^2$ of this regression.
$$\text{VIF} = \frac{1}{1 - r^2_{(j)}}$$
We want the lowest VIF.

› **Coeficient of correlation :**
$$r = \frac{\text{Cov}(X,Y)}{\sigma_x \sigma_y} = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum (x_i - \bar{x})^2 \sum (y_i - \bar{y})^2}}$$

› For two-feature model $R^2_{(y)} = r^2$.

# Lesson 49 : Validation

› The **Hat matrix** put a hat on $y$ since $\hat{\mathbf{y}} = \mathbf{Hy}$.
$$\mathbf{H} = \mathbf{X}(\mathbf{X^\mathsf{T} X})^{-1} \mathbf{x^\mathsf{T}}$$

› It follow that $\text{Var}(\hat{\varepsilon}) = (\mathbf{I} - \mathbf{H})\sigma^2$

› For simple linear regression :
$$h_{ii} = \frac{1}{n} + \frac{(x_i - \bar{x})^2}{S_{xx}}$$

› The **studentized residuals** are define as
$$r_i = \frac{\hat{\varepsilon}_i}{\sqrt{S^2(1 - h_{ii})}}$$
where $h_{ii}$ is the **leverage**. Average leverage should be at $\frac{p'}{n}$. $\sum h_{ii} = p'$

› A **influence point** is a observatio that influence a lot $y$. A **outliers** is a observation that have $|r_i| > 3$.

› Two mesure for influence point.

   – $\text{DFITS}_i = r_i \sqrt{\frac{h_{ii}}{1 - h_{ii}}}$

   – **Cook :** $D_i = \frac{\sum (\hat{y}_j - y_{j(i)})^2}{p' S^2} = r_i^2 \frac{h_{ii}}{p'(1 - h_{ii})}$
   $D_i > 1$ is too high.

# Lesson 50 : Prediction

› A **confidence interval** for predicted values.
$$y^* \in \hat{y}^* \pm t_{(n-2)} \sqrt{S^2 \left( \frac{1}{n} + \frac{(x^* - \bar{x})^2}{S_{xx}} \right)}$$

› A **prediction interval** for predicted values.
$$y^* \in \hat{y}^* \pm t_{(n-2)} \sqrt{S^2 \left( 1 + \frac{1}{n} + \frac{(x^* - \bar{x})^2}{S_{xx}} \right)}$$

# Lesson 51 : ANOVA

**One-factor ANOVA**

$$SST = SSE + SSTR$$

| Model | Sum of square | Deviance |
|-------|--------------|----------|
| $Y = \mu + \varepsilon_{ij}$ | SST | $D_M$ |
| $Y = \mu_i + \varepsilon_{ij}$ | SSE | $D_A$ |

› **Within sum of square**
$$SSE = \sum_{i=1}^{k} \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_{i\Sigma})^2$$

› **Between sum of square**
$$SSTR = \sum_{i=1}^{k} n_i (\bar{y}_{i\Sigma} - \bar{y}_{\Sigma\Sigma})^2 = \sum_{i=1}^{k} \left( \frac{y_{i\Sigma}^2}{n_i} \right) - n\bar{y}_{\Sigma\Sigma}^2$$

› **Total sum of square**
$$SST = \sum_{i=1}^{k} \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_{\Sigma\Sigma})^2 = \sum_{j=1}^{n_i} (y_{ij}^2) - n\bar{y}_{\Sigma\Sigma}^2$$

› **Fishier test**
$$F_{(k-1, n-k)} = \frac{SSTR/(k-1)}{SSE/(n-k)} = \frac{(D_M - D_A)/(k-1)}{D_A/(n-k)}$$
where $D_M$ is the *scale deviance* of the minimal model.

**Two-factor ANOVA without replication**

$$SST = SSE + SSTR + SSB$$

| Model | Sum of square (DF) |
|-------|-------------------|
| $Y = \mu + \varepsilon_{ij}$ | SST$(bk-1)$ |
| $Y = \mu + \alpha_i + \varepsilon_{ij}$ | SSTR $(k-1)$ |
| $Y = \mu + \beta_j + \varepsilon_{ij}$ | SSB$(b-1)$ |
| $Y = \mu + \alpha_i + \beta_j + \varepsilon_{ij}$ | SSE$(k-1)(b-1)$ |

› The formula are the same but $n_i$ is $k$ for SSTR and $b$ for SSB.

**Two-factor ANOVA with replication**

› To test interaction :
$$F_{(I-1)(J-1), IJ(K-1)} = \frac{(D_I - D_s)/(I-1)(J-1)}{D_s / IJ(k-1)}$$

› To test factor A :
$$F_{(I-1), IJ(K-1)} = \frac{(D_B - D_I)/(I-1)}{D_s / IJ(k-1)}$$

› To test factor B :
$$F_{(J-1), IJ(K-1)} = \frac{(D_M - D_B)/(J-1)}{D_s / IJ(k-1)}$$
where $D_s$ is the satured model, I for additive model.

› ANCOVA

# Lesson 52 : Measures of Fit II

For **contingencies table** with binomial or poisson distribution.

› Pearson : $\chi^2 = \sum \frac{(O_i - E_i)^2}{E_i} \sim \chi^2_{(n-p')}$

› Likelihood ratio chi-square :
$$C = 2[\ell - \ell_{\min}] \sim \chi^2_{(p'-1)}$$

› **Pseudo**$R^2$ : pseudo$R^2 = \frac{\ell_{\min} - \ell}{\ell_{\min}}$

**Residus**

› Pearson residual : $X_k = \frac{y_i - \hat{\mu}_i}{\sqrt{\text{Var}(\hat{\mu}_i)}}$

› Deviance residual : $d_k = s_k \sqrt{\text{deviance}}$
where $s_k$ is the signe of $y_k - \hat{y}_i$

› To standartize them, divide by $\sqrt{1 - h_{ii}}$

# Lesson 53 : Resampling Methods

› **Cross-Validation :**
$$CV_{(K)} = \frac{1}{k} \sum_{i=1}^{k} MSE_i$$
As $k \to n$ bias $\Downarrow$ $\text{Var}(CV_k) \Uparrow$
If $k = n$ then is the LOOCV statistic.

› LOOCV for least-square regression :
$$CV_{(K)} = \frac{1}{n} \sum_{i=1}^{n} \left( \frac{\varepsilon_i}{1 - h_{ii}} \right)^2$$

› **Bootstap :**
$$SE_B(\alpha) = \sqrt{\frac{1}{1-B} \sum_{i=1}^{B} (\hat{\alpha} - \bar{\alpha})^2}$$

# Lesson 54 : Subset Selection

Using a lot of feature will result of lower standard error on training data, but poor prediction. We need to keep only the feature that truly impact the response.

› **Subset selection** For $k$ possible feature, $2^k$ different model are possible.

   – For 2 model with same number of feature, we take the one with lowest $SSE$.

   – Otherwise, we compare with : Mallow's $C_p$, AIC, BIC and adjusted $R^2$.

› **Foward stepwise selection** consist of starting with the null, then fit $k$ models with one variable and select the best base on SSE, then fit $k-1$ variables and so on. We obtain $k+1$ model, the best for each number of predictor, and select the final one with cross-validation or the 4 statistics. For categorial variables, each categorie is added independently.

› **Total fitted model :**

   – Foward : $1 + \sum_{i=0}^{\min(p,n)} (\min(p, n) - i)$

   – Backward : $1 + \sum_{i=1}^{\min(p,n)} i$

**Choosing the best model**

› **Cross-validation** is the more accurate.

› **Mallow's $C_p$ :** $C_p = \frac{1}{n}(SSE + 2p\hat{\sigma}^2)$
IF $\hat{\sigma}^2$ is unbiased then $C_p$ is unbiased.

› **Adjested $R^2$ :** $R^2_a = 1 - \frac{MSE}{MST}$

› We want the lowest Mallow's $C_p$, AIC, BIC and the heighest $R^2_a$.

# Lesson 55 : Shrinkage and Dimension Reduction

> **Ridge Regression :** Minimize
$$\left( \sum_{i=1}^{n} y_i - \beta_0 - \sum_{j=1}^{p'-1} \beta_j x_{ij} \right) + \lambda \sum_{j=1}^{p'-1} \beta_j^2$$

> **Lasso Regression :** Minimize
$$\left( \sum_{i=1}^{n} y_i - \beta_0 - \sum_{j=1}^{p'-1} \beta_j x_{ij} \right) + \lambda \sum_{j=1}^{p'-1} |\beta_j|$$

> **Standart Predictors** $\tilde{x} = \dfrac{x_{ij}}{\sqrt{\frac{1}{n}\sum(x_{ij}-\bar{x})^2}}$

$$\lambda \to \infty \Leftrightarrow \beta_j \to 0$$
$$\lambda \to 0 \Leftrightarrow \beta_j \to \hat{\beta}_j^{\text{normal}}$$

| PCA | Partial Least Square |
|---|---|
| unsupervised | supervised |
| variables are linear combianaire of the original | |
| Higher bias | Lower bias |
| Lower variance | Higher variance |

# Lesson 56 :Extension to the Linear Model

> **Extention :** These type can be treate as same as GLM. $y_i = \beta_0 + \beta_1 b_1(x_i) + \beta_2 b_2(x_i) + ... + \varepsilon_i$
For **polynomial regression**, $b_j(x) = x^j$.
For **piecewise constant regression**
$b_j(x) = \mathbb{1}_{\{a \le x < b\}}(x)$

> **Generalized Additive Model :**
$$y_i = \beta_0 + \sum_{j=1}^{p} f_i(x_{ij}) + \varepsilon_i$$

– Allows nonlinear fits for each explanatory variable.

– Effet on each explanatory is separate, so easily identifiable.

– Does not allow foe effect of interaction among variable.

# Lesson 57 : Trend and Seasonality

> **Trend** measures the amount by which the serie increase from period to period.

> **Seasonal** variation measure cycle within a year.

> **Decomposition models**

– Additive Model : $x_t = m_t + s_t + z_t$

– Multiplicative Seasonality : $x_t s_t + z_t$

– Multiplicative Model : $x_t = m_t s_t z_t$

> **Centered moving average :**
$\hat{m}_t = \dfrac{0.5m_{t-k}+m_{t-k+1}+...+m_t+...+m_{t+k-1}+0.5m_{t+k}}{2k}$

> **Seasonal variation factor :**

– Additive Seasonality : $\hat{s}_t = x_t - \hat{m}_t$
Ajusted so that $\sum(s_t + c) = 0$.

– Multiplicative Seasonality $\hat{s}_t = \dfrac{x_t}{\hat{m}_t}$
Ajusted so that $\sum \dfrac{(\hat{s}_t+c)}{n} = 1$.

# Lesson 58 : correlation

> if $\mu(t)$ and $\sigma^2(t)$ does not vary with $t$ then the time serie is **second order stationnary**

> **Variance :** $\sigma^2(t) = \mathrm{E}\left[(x_t - \mu(t))^2\right]$

**Stationnary Time serie**

> **sample variance** $s^2 = \dfrac{1}{n-1} \sum_{i=1}^{n} (x_t - \bar{x})^2$

> **Covariance** at lag $k$ :
$\mathrm{Cov}(x_t, x_{t+k}) = \gamma_k = \mathrm{E}\left[(x_t-\mu)(x_{t+k}-\mu)\right]$ (**acvf**)
$c_k = \frac{1}{n}\sum_{i=1}^{n-k}(x_t-\bar{x})(x_{t+k}-\bar{x})$    (**sample acvf**)

> **Auto-correration**
$\rho_k = \dfrac{\mathrm{Cov}(x_t, x_{t+k})}{\sigma^2}$    (**acf**)
$r_k = \dfrac{c_k}{c_0}$    (**sample acf**)

**Relationships of different time serie**

> A **leading variable** is one that impact another.

> **Cross-covariance**
$\gamma_k(x, y) = \mathrm{E}\left[(x_{t+k}-\mu_x)(y_t-\mu_y)\right]$    (**ccvf**)
$c_k = \dfrac{1}{n}\sum_{i=1}^{n-k}(x_{t+k}-\bar{x})(y_t-\bar{y})$    (**sample ccvf**)

> **Cross-correration**
$\rho_k(x, y) = \dfrac{\gamma_k(x,y)}{\sigma_x \sigma_y}$    (**ccf**)
$r_k = \dfrac{c_k(x,y)}{\sqrt{c_0(x,x)c_0(y,y)}}$    (**sample ccf**)

> Notice
$$\gamma_k(x, y) = \gamma_{-k}(x, y)$$
$$\rho_k(x, y) = \rho_{-k}(x, y)$$
$$c_0(x, x) = c_0$$

# Lesson 59 : White Noise and Random Walks

> **White noise** each term are independant and variance $\sigma^2$. The correlogram has autocorrelations all close to 0 except for $r_0$.
$$w \sim N(0, \sigma^2)$$

> A **Random Walks** is a nonstationary time series which is the accumulation of white noise. The correlogram will decrease slowly from 1 to 0.
$$x_1 = w_1$$
$$x_t = x_{t-1} + w_t$$
with
$$\mu(t) = 0$$
$$\sigma^2(t) = t\sigma_w^2$$
$$\gamma_k(t) = t\sigma_w^2$$
$$\rho_k(t) = \dfrac{1}{\sqrt{1+\frac{k}{t}}}$$

> A **Walk with drift** drift the mean $\mu(t) = t\delta$ by don't affect variance and autocorrelations.
$$x_t = x_{t-1} + \delta + w_t$$

# Lesson 60 : Autoregressive Models

> An **autoregressive** model of order ($p$), or AR(p) is a time series where term may be expressed in term of previous terms plus white noise.
$$x_t - \mu = \alpha_1(x_{t-1} - \mu) + \alpha_2(x_{t-2} - \mu)$$
$$+ ... + \alpha_p(x_{t-p} - \mu) + w_t$$

> An AR(1) process is stationary if $|a| < 1$. correlogram is deacreasing exponentially. For a stationary AR(1) process
$$\mu_k = 0$$
$$\gamma_k = \dfrac{\alpha^k \sigma_w^2}{1 - \alpha^2}$$
$$\rho = \alpha^k$$

> Notation : $\mathbf{B}^k x_t = x_{t-k}$
$$w_t = x_t - \alpha_1 x_{t-1} - \alpha_2 x_{t-2}$$
$$= (\alpha_2 \mathbf{B}^2 - \alpha_1 \mathbf{B} + 1)x_t$$
$$= \theta_p(\mathbf{B})x_t$$

where $\theta_p(\mathbf{B})$ is the **characterictic equation**.

> Testing stationarity : Root < 1

(given)  $x_t = \alpha_1 x_{t-1} + \alpha_2 x_{t-2} + w_t$

(solve)  $\theta_p(\mathbf{B}) = 0$

(answer)  If $|\mathbf{B}| > 1$, the process is stationary.

> tips : For 2 param :
$$\alpha_2 - \alpha_1 < 1$$
$$\alpha_2 + \alpha_1 < 1$$
$$|\alpha_2| < 1$$

> Forecast $\hat{x}_{n+1|n}$ is the same equation omitting $w_t$.

# Lesson 61 : Regression

> Variance of sample mean with correlation is given by
$$\mathrm{Var}(\bar{x}) = \dfrac{\sigma^2}{n}\left(1 + 2\sum_{k=1}^{n-1}\left(1-\dfrac{k}{n}\right)\rho_k\right)$$

> **Harmonic Seasonal model**
$$x_t = m_t + \sum_{i=1}^{[S/2]} s_i \sin(2\pi i t/s)$$
$$+ c_i \cos(2\pi i t/s) + z_t$$

> Forecast correction

– Lognormal : $e^{\sigma^2/2}$

– Empirical : $\dfrac{\sum e^{z_t}}{n}$

## Lesson 62 : Moving Average Models

> A **moving average** time serie (MA(q)) is alway stationary. It define as
$$x_t = \mu + w_t + \beta_1 w_{t-1} + ... + \beta_q w_{t-q}$$
$$= \mu + \phi(\mathbf{B}) w_t$$
with
$$\mu(t) = 0$$
$$\gamma_k = \sigma_w^2 \sum_{i=0}^{q-k} \beta_i \beta_{i+k} \quad \beta_0 = 1$$

and $\gamma_k = 0$ for $k > q$ so MA(q) may be good fit is we observe $\gamma_q = 0$ in correlogram.

> $q$ beta $+ \mu + \sigma_w^2 = q + 2$ parameters fit.

> A MA(q) is **Inversible** if all the root of $\phi(\mathbf{B})$ are $|\mathbf{B}| > 1$

> Express MA(q) in form of AR($\infty$). If $\phi(\mathbf{B})$ is reversible :
$$\frac{1}{1+x} = 1 - x + x^2 - x^3 + x^4 + ..$$
$$\frac{1}{1-x} = 1 + x + x^2 + x^2 + x^4 + ...$$

> ARIMA with $p = d = 0$ is a MA(q) model.

> conditional sum of squared residuals : $\sum w_t^2$

## Lesson 63 : ARMA Models

> The ARMA(p,q) models :
$$x_t = \alpha_1 x_{t-1} + ... + \alpha_p x_{t-p} + \beta_1 + w_{t-1} + ... + \beta_q w_{t-q} + w_t$$
$$\theta_p(\mathbf{B}) x_t = \phi_q(\mathbf{B}) w_t$$

> The process is stationary if all roots of $\theta(x) > 1$ and the process is inversible if all roots of $\phi(x) > 1$

$$\gamma_0 = \sigma_w^2 \left( \frac{1 + 2\alpha\beta + \beta^2}{1 - \alpha^2} \right)$$

$$\gamma_k = \sigma_w^2 (\alpha + \beta) \alpha^{k-1} \left( \frac{1 + \alpha\beta}{1 - \alpha^2} \right)$$

$\rho_k = \alpha \rho_{k-1}$ for $k \geq 2$.

> If the process is stationary, $E[x_t] = E[x_{t-1}]$.

## Lesson 64 : ARIMA and SARIMA models

> $\nabla x_t + x_t - x_{t-1} = (1 - \mathbf{B}) x_t$

> An **ARIMA** model is a nonstationary process. If $x_t$ is an ARIMA model, then $y_t = \nabla^d x_t$ is an ARMA(p,q). Then the ARIMA(p,d,q) is
$$\theta(\mathbf{B})(1 - \mathbf{B})^d x_t = \phi(\mathbf{B}) w_t$$
  - With no MA(q), this is ARI(p,d)
  - With no AR(p), this is IMA(d,q)

> An **SARIMA** model is a ARIMA with seasonal effect.

> To forecast, we take the difference and then forecast ARMA(p,q) model.

# Appendix

## Inverting a matrix

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1} = \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$$

<mark>Ajouter pour une matrice 3x3</mark>

## Synthetic Division

**Exemple :** Factorize $x^3 - 12x^2 - 81$

|   | 1 | -12 | 0 | -81 |
|---|---|-----|---|-----|
| 3 |   | 3 | -27 | -81 |
|   | 1 | -9 | -27 | 0 |

then, $x^3 - 12x^2 - 81 = (x - 3)(x^2 - 9x - 27)$

## Deductible and Limite

$$X = \min(X; d) + \max(0; X - d)$$
$$E[X] = E[\min(X; d)] + E[\max(0; X - d)]$$
$$= E[(X \wedge d)] + E[(x - d)_+]$$
$$= E[(X \wedge d)] + e_x(d) \cdot S_x(d)$$

## Statistic Order

> $Y_1 = \min(X_1, ..., X_n)$
$$f_{Y_1}(y) = n f(y) [S(y)]^{n-1}$$
$$S_{Y_1}(y) = \prod_{i=1}^{n} \Pr(X_i > x)$$

> $Y_n = \max(X_1, ..., X_n)$
$$f_{Y_n}(y) = n f(y) [F(y)]^{n-1}$$
$$F_{Y_n}(y) = \prod_{i=1}^{n} \Pr(X_i \leq x)$$

> $Y_k \in (Y_1, ..., Y_k, ..., Y_n)$
$$f_{Y_k}(y) = \frac{n! \cdot f(y) [F(y)]^{k-1} [S(y)]^{n-k}}{(k-1)!(n-k)!}$$
$$F_{Y_k}(y) = \Pr(\text{at least k of n } X_i \text{ are} \leq y)$$
$$= \sum_{i=k}^{n} \binom{n}{i} [F(y)]^i [S(y)]^{n-j}$$

> $x + y = \min(x, y) + \max(x, y)$, since one is for sure the max and the other the min.

## Mode : Most likely probability

> $g(x) = f(x)$ or some time $g(x) = \ln f(x)$
> **Mode** is the $x$ that respects : $g'(x) = 0$
## Normal Approximation

> $F_X(x) = \Phi \left( \frac{X - E[X]}{\sqrt{\text{Var}(X)}} \right)$

> **Continuity correction** is necessary when X is discrete. $F_X(x) = \Phi \left( \frac{(X \pm k) - E[X]}{\sqrt{\text{Var}(X)}} \right)$ where $k$ is the mid-point of the discrete value.

## Discrete Cumulative Function

$$\Pr(X = x) = \begin{cases} 0.10, & x = 0 \\ 0.30, & x = 5 \\ 0.15, & x = 10 \\ 0.25, & x = 15 \\ 0.20, & x = 20 \end{cases}$$

$$\Pr(X \leq x) = \begin{cases} 0.10, & 0 \leq x < 5 \\ 0.40, & 5 \leq x < 10 \\ 0.55, & 10 \leq x < 15 \\ 0.80, & 15 \leq x < 20 \\ 1, & x \geq 20 \end{cases}$$

## Contract

> **Deductible(d)**

> **Maximum(u)**

> **Inflation(r)**

> **Coinsurance($\alpha$)**

$$Y = \begin{cases} 0 & x \leq \frac{d}{1+r} \\ \alpha[(1+r)x - d] & \frac{d}{1+r} < x < \frac{u}{1+r} \\ \alpha[u - d] & x \geq \frac{u}{1+r} \end{cases}$$

Warning : The maximal don't include the deductible.

# Moments

> $k^e$ moment about the origin. $\mu'_k = E\left[X^k\right]$

> $k^e$ moment about the mean. $\mu_k = E\left[(X-\mu)^k\right]$

> The **Skewness** moment give infomation about the asymmetry of the distribution. If $S_{sk} = 0$, the distribution is normal.
$$S_{sk} = E\left[\left(\frac{X-\mu}{\sigma^2}\right)^3\right]$$

> The **kurtosis** moment give infomation about the flattening of the distribution. If $S_{ku} = 0$, the distribution is normal.
$$S_{ku} = E\left[\left(\frac{X-\mu}{\sigma^2}\right)^4\right]$$

> The **coefficient of variation** give information about the dispersion of the distribution.
$$CV = \frac{\sigma}{E[X]}$$

# Transformations of distribution

> Lognormal : $Y = e^X$, where
$$Y \sim \text{Lognormal}(\mu, \sigma)$$
$$X \sim \text{Normal}(\mu, \sigma)$$

> Inverse Exponential : $Y = \frac{1}{X}$, where
$$Y \sim \text{Inverse Exponential}(1/\theta)$$
$$X \sim \text{Exponential}(\theta)$$

> Weibull : $Y = X^{1/\tau}$, where
$$Y \sim \text{Weibull}(\sqrt[\tau]{\theta})$$
$$X \sim \text{Exponential}(\theta)$$

# Parameter interpretation

> **Scale parameter** $(\theta, \beta, \sigma)$ **:** Affect the spread of the distribution.

> **Rate parameter** $(\lambda)$ **:** Affect the rate of data at mean. $(1/\text{scale})$

> **Shape parameter** $(\alpha, \tau, \gamma)$ **:** Affect the shape rather then simply shift the distribution.

# Produit de convolution

The convolution of 2 random variable is difine as the sum of the two.

$$f_{X_1+X_2}(x) = \int_{-\infty}^{\infty} f_{X_1}(x-s) f_{X_2}(s)\,ds$$

$$F_{X_1+X_2}(x) = \int_{-\infty}^{x} F_{X_1}(x-s) f_{X_2}(s)\,ds$$

# Shifting Exponential

$$f(x;\theta;d) = \frac{1}{\theta} e^{-(x-d)/\theta}$$
$$E[x] = \theta + d$$
$$\text{Var}(x) = \theta^2$$

# Norme d'un vecteur

$$\ell_1 = x_1 + x_2 + \ldots + x_n$$
$$\ell_2 = \sqrt{x_1^2 + x_2^2 + \ldots + x_n^2}$$

# Greedy algorithm

A group of $n$ peoples is to be assigned to $k$ job, one to each job. The cost of job j is $c_{ij}$ if person i is assigned. Select the assignement to have the minimal cost. We fixe the job or the people such as the $\min(n, k)$ and take the **minimum** cost for this personne(job).

$$c_{ij} \sim \text{Exp}(\theta)$$

$$E[\textbf{Total cost}] = \sum_{i=1}^{\min(n,k)} \frac{\theta}{\max(n,k)}$$

# Potential outliers

Let $Q_1$ and $Q_2$ be the $25^e$ and the $75^{75}$ quantile. Then $h = 1.5(Q_3 - Q_1)$. Observation are potential outliers if their are not in

$$(Q_1 - h, Q_3 + h)$$

# Test III

Type III tests are tests on variable or set of variable that assume that all other variables are present in the model. The **Wald** test is type III.

# Overdispersion

If the variance of the observation is **higher** than indicated by the binomial or poisson model. **Hight diviance** may indicate Overdispersion. We can solve it with **quasi-likelihood** : $\phi \text{Var}(y)$. This don't affect the fit but many statistic like Pearson. For Poison, we can use a Binomial Negative model.
